

# SAT SUBMISSION - V

Team No.: 09

Date of submission: 03/ 12/ 2022

Name of the student: BHARATHI SHRINIVASAN T R

ID No.: 2022H1400182P

## **Paper Title with citation:**

Vishal Kumar, Shailendra Mishra, Narottam Chand, Faculty of Department of Computer Science (BTKIT-Dwaeahat, NIT-Hamirpur), India "**Applications of VANETs: Present & Future**" proceedings of 2013 5th Communications and Network: 12-15, under Scientific Research copyright.

## **Motivation for selection of the paper:**

In this paper, we wanted to answer a very fundamental question- *What information do the VANET via V2V or V2I transmit? And what are the applications and possibilities of using VANET?* This paper is from the Communications and Network journal. It addresses some of the details of VANET applications and can light clarity to arrive at the answer to the question.

## **Summary:**

As an introduction part, the author has shown some statistics i.e., Due to road accidents direct/indirectly, around 43000 deaths/year, 2.7 million people injuries/year and \$230 billion social cost as per NHTSA record. The implication is that the increasing vehicle count day-by-day requires some intelligence to reduce the possibility of accidents. VANET adds this ability to vehicles. The vehicular safety consortium and vehicle infrastructure initiative, along with giant vehicle manufacturing companies, are setting in research and development of applications and productive insights from the usage of VANETs – use of mobile ad-hoc networks by on-board unit (OBU) in a vehicle from network established by roadside unit (RSU) without any other infrastructure.

This paper detailed the categories of various possible applications of vehicular networks and their implications in the real world. The applications would tell us the kind of data/information that would be communicated between vehicle OBU, and infrastructure RSU via V2V, V2I networks. Some of the approved standards for vehicular communication are DSRC (Dedicated short range communication) and IEEE 802.11p WAVE (wireless access for vehicular environment) for physical and MAC layer. WAVE process allocates DSRC spectrum band of 5.9Ghz with BW of 75Mhz. The main objective of design is low connection setup delay, fast network recognition and differentiation of applications for normal and emergency use. To address the emergency communications, and alerting message transmission, and trans-received between fast-moving vehicles. The cellular system goal is different as it is soft-real time system service but DSRC-based VANET at emergency has to serve hard-deadline. In section 2, various characteristics of VANET has explained i.e., Highly dynamic topology, robust to frequent disconnect network, mobility modelling and prediction, Communication environment, Hard-delay constrain, OBU interaction, and power consumption. In section 3 description of various applications using VANET is detailed. The author has categorised applications into Safety oriented (i.e., Real-time traffic, cooperative collision warning, traffic vigilance etc), commercial oriented (i.e., remote vehicle diagnostics, multi-media access, digital map data service), convenience applications (mainly deals in traffic management with the motto to enhance traffic flow efficacy covering route diversion information, Electronic toll collection, parking management), lastly Productive applications which encompasses tasks related to environment benefit (fuel consumption, gas emission quality). In this section, the author has briefed some of the applications. Very interesting applications which I found were, one from Real-time traffic management: RSU serve as the repository to monitor the vehicle count and vehicles OBU can use this info priori in find the efficient route and thereby increase traffic flow. Other application is post-crash notification- sending post-accident info to nearby police and emergency team. Traffic vigilance system, which is automates the vigilance and fining. Remote diagnostics application- where vehicle company can monitor, diagnosis remotely to assist clients post sale. In the next section, the author has detailed future of VANETs. Some of the noteworthy are the current adaptation of VANET applications by various departments, NHAI-highway authority India planning to replace manual toll collection to complete ETC electronic tolling collection system, which would use RFID tag in vehicle's OBU and tag reader in RSU at plaza. Australian police in NSW and Victoria have come up with laser camera system installed in RSU servicing traffic

vigilance. The future of VANETs is secure undoubted. The challenge would be the transition of phase from manual to automated traffic management system and its commercial adaptations by market.

My conclusion – The author has described the architecture, standards & protocol of vehicular ad-hoc networks, followed by the classification of various categories of applications it could be employed for. These applications are implement using the VANET platform, thus answering the question that we were searching answer. Further, author has also emphasised on the kind of cyber challenges that would be involved in such platform.

## ABSTRACT

The Vehicular Safety Consortium (VSC), the Crash-Avoidance Metrics Partnership (CAMP) consortium and the Vehicle Infrastructure Initiative (VII) [1] along with the giants of the light-duty vehicle manufactures, are working to develop pre-competitive safety technologies and various applications that can be offered in Vehicular ad-hoc Networks (VANETs), a special kind mobile ad-hoc networks where wireless equipped element called on-board unit (OBU) in vehicles form a network with the Roadside unit (RSU) without any additional infrastructure. In this paper, we are primarily categorizing various possible applications of vehicular network, along with its features, and implementations in the real world.

**Keywords:** Roadside Unit; WAVE; VSC; CAMP; VII

## 1. Introduction

As the vehicles are growing, the possibility of accidents has also increased. According to the *National Highway Traffic Safety Administration (NHTSA)* [1,4], there are around 43000 deaths /year, 2.7 million people injured/year and \$230 billion social cost. It is required to make our vehicles a bit intelligent so that we can reduce the possibilities of accidents. A vehicular ad-hoc network (VANET) adds ability in the vehicles. Dedicated Short Range Communications (DSRC) and IEEE 802.11p Wireless Access for Vehicular Environment (WAVE) [2, 3] have been approved as standards for PHY and MAC layers for vehicular networks. The IEEE 802.11p WAVE standardization process originates from the allocation of the DSRC spectrum band of 5.9 GHz with a bandwidth of 75 MHz and approximate range of 1000 m. The main aim of DSRC and the IEEE 802.11p WAVE standard is to define rules for low connection setup delay, fast network recognition and the differentiation of applications for normal and emergency use. They allow a high throughput communication with low delay among vehicles. This leads to efficient emergency communications. For example, in the case of accidents, an alerting message transmitted among vehicles can be faster and, thus, well-timed, rather than communications sent through an infrastructure network (such as cellular systems).

## 2. Characteristics of Vanets

Many different and sometimes competing design goals have to be taken into account for VANETs to ensure

their commercial success. When equipped with WAVE (Wireless Access for Vehicular Environment, a novel type of wireless access dedicated to vehicle-to-vehicle and vehicle-to-roadside communications), in **Figure 1** it forms a highly dynamic network.

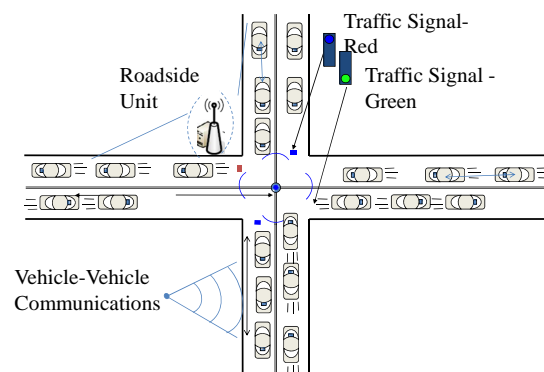

Although, some characteristics of VANETs resembles with the characteristics of MANETs [6, 8] but there are specific features which can be categorized as follows:

### 1) Highly dynamic topology

The high speed of the vehicles along with the availability of choices of multiple paths defines the dynamic topology of VANETs.

### 2) Frequent disconnected network

The high speed of the vehicles in one way defines the dynamic topology whereas on the other hand necessitates the frequent requirements of the roadside unit lack of which results a frequent disconnections.

**Figure 1. Vehicular Ad Hoc Networks.**

### 3) Mobility modeling and Prediction

The prediction of vehicle position and their movements is very difficult. This features of mobility modeling and prediction in VANETs is based on the availability of predefined roadmaps models. The speed of the vehicles is again an important for efficient network design.

### 4) Communication Environment

Once we are having a mobility model, yet we are not done. As the mobility model may have different features depending upon road architecture, highways, or city environments. Communicating in these situations has to be taken care.

### 5) Hard delay constraints

At the time of emergency, delivery of messages on time is a critical problem. Therefore, handle such situations rather talking only about high data rates in not sufficient.

### 6) Interaction with onboard sensors

Sensors are the mode of communications. Sensors can read data related to velocity of the vehicle, direction and can communicate to the data center. Thus sensors can be used in link formation and in routing protocols.

### 7) Unlimited Battery Power and Storage

Nodes in VANETs do not suffer power and storage limitation as in sensor networks; therefore optimizing duty cycle is not as relevant as in sensor networks.

## 3. Applications of Vanets

The RSU can be treated as an access point or router or even a buffer point which can store data and provide data when needed [5]. All data on the RSUs are uploaded or downloaded by vehicles. A classification of applications is also done by [20] as Car to Car Traffic applications, Car to Infrastructure applications, Car to Home applications and Routing based applications. The authors in [19] discusses about the various attacks based on their classification. Based on the type of communication either V2I or V2V, we are arranging the applications of VANETs into following classes:

- 1) Safety oriented,
- 2) Commercial oriented
- 3) Convenience oriented and
- 4) Productive Applications

### 3.1. Safety Applications

Safety applications include monitoring of the surrounding road, approaching vehicles, surface of the road, road curves etc. The Road safety applications can be classified as:

1) *Real-time traffic*: The real time traffic data can be stored at the RSU and can be available to the vehicles whenever and wherever needed. This can play an impor-

tant role in solving the problems such as traffic jams, avoid congestions and in emergency alerts such as accidents etc.

2) *Co-operative Message Transfer*: Slow/Stopped Vehicle will exchange messages and co-operate to help other vehicles. Though reliability and latency would be of major concern, it may automate things like emergency braking to avoid potential accidents. Similarly, emergency electronic brake-light may be another application.

3) *Post Crash Notification*: A vehicle involved in an accident would broadcast warning messages about its position to trailing vehicles so that it can take decision with time in hand as well as to the highway patrol for tow away support as depicted in **Figure 2**.

4) *Road Hazard Control Notification*: Cars notifying other cars about road having landslide or information regarding road feature notification due to road curve, sudden downhill etc.

5) *Cooperative Collision Warning*: Alerts two drivers potentially under crash route so that they can mend their ways [7].

6) *Traffic Vigilance*: The cameras can be installed at the RSU that can work as input and act as the latest tool in low or zero tolerance campaign against driving offenses [9].

## 3.2. Commercial Applications

Commercial applications will provide the driver with the entertainment and services as web access, streaming audio and video. The Commercial applications can be classified as:

- 1) *Remote Vehicle Personalization/ Diagnostics*: It helps in downloading of personalized vehicle settings or uploading of vehicle diagnostics from/to infrastructure.
- 2) *Internet Access*: Vehicles can access internet through RSU if RSU is working as a router.

**Figure 2. Emergency situation Notification.**

3) *Digital map downloading*: Map of regions can be downloaded by the drivers as per the requirement before traveling to a new area for travel guidance. Also, Content Map Database Download acts as a portal for getting valuable information from mobile hot spots or home stations.

4) *Real Time Video Relay*: On-demand movie experience will not be confined to the constraints of the home and the driver can ask for real time video relay of his favorite movies.

5) *Value-added advertisement*: This is especially for the service providers, who want to attract customers to their stores. Announcements like petrol pumps, highways restaurants to announce their services to the drivers within communication range. This application can be available even in the absence of the Internet.

### 3.3. Convenience Applications

Convenience application mainly deals in traffic management with a goal to enhance traffic efficiency by boosting the degree of convenience for drivers. The Convenience applications can be classified as:

1) *Route Diversions*: Route and trip planning can be made in case of road congestions.

2) *Electronic Toll Collection*: Payment of the toll can be done electronically through a Toll Collection Point as shown in **Figure 3**. A Toll collection Point shall be able to read the OBU of the vehicle. OBUs work via GPS [17] and the on-board odometer or techograph as a back-up to determine how far the Lorries have travelled by reference to a digital map and GSM to authorize the payment of the toll via a wireless link. TOLL application is beneficial not only to drivers but also to toll operators.

3) *Parking Availability*: Notifications regarding the availability of parking in the metropolitan cities helps to find the availability of slots in parking lots in a certain geographical area.

4) *Active Prediction*: It anticipates the upcoming topography of the road, which is expected to optimize fuel usage by adjusting the cruising speed before starting a descent or an ascent. Secondly, the driver is also assisted [10].

**Figure 3. Electronic Toll Collection in India.**

### 3.4. Productive Applications

We are intentionally calling it productive as this application is additional with the above mentioned applications. The Productive applications can be classified as:

1) *Environmental Benefits*: AERIS research program [11] is to generate and acquire environmentally-relevant real-time transportation data, and use these data to create actionable information that support and facilitate “green” transportation choices by transportation system users and operators. Employing a multi-modal approach, the AERIS program will work in partnership with the vehicle-to-vehicle (V2V) communications research effort to better define how connected vehicle data and applications might contribute to mitigating some of the negative environmental impacts of surface transportation.

2) *Time Utilization*: If a traveler downloads his email, he can transform jam traffic into a productive task and read on-board system and read it himself if traffic stuck. One can browse the Internet when someone is waiting in car for a relative or friend.

3) *Fuel Saving*: When the TOLL system application for vehicle collects toll at the toll booths without stopping the vehicles, the fuel around 3% is saved, which is consumed when a vehicles as an average waits normally for 2-5 minutes.

## 4. Future

As mobiles are familiar and used by us in our day to day life, similarly the future of VANETs is undoubtedly secure. It has become the part of the government projects. In India, National Highways Authority of India (NHAI) [12] is planning to replace manual toll collections at plazas with electronic toll collection (ETC) systems across the country. The ETC system will be based on radio frequency identification (RFID), which will be complemented by a wireless on-board unit (OBU) on a vehicle, as well as a stationery roadside unit (RSU) at the toll plaza.

Australian police in New South Wales (NSW) and Victoria are considering the introduction of a new type of laser speed camera, which can catch drivers using mobile phones, as well as speeding motorists from half a mile away [13]. The cameras, known as Concept II, have been manufactured by Tele-Traffic UK and are already in use by UK's Dorset police as the latest tool in their zero tolerance campaign against driving offenses. Similarly, various projects are running in various countries to employ VANETs in traffic safety and efficiency.

There are many other challenges left that will have a strong influence on the future of VANETs. Although, to show the impact of VANETs on traffic safety, and efficiency, a number of simulators are available namely EstiNet, ns-2, TRANS [14-16] and many more, but study of

driver's behavior and reaction [18] when additional information is provided through VANETs is also a challenge. The adoption of VANETs in the market is another challenge as there are many players in the game.

## 5. Conclusions

In this paper, we first gave a description of architecture, standards & protocols of vehicular ad hoc networks, followed by the characteristics described in Section II. Section III describes various applications based on its classification. Section IV is giving the implementation of applications at present and in future in countries that are deploying VANETs in one way or the other. Although the works are numerous, there are still issues which may be untouched. However, we want to clarify that the list of applications identified here is not exhaustive. We hope, at least, the study in this paper would contribute in new research directions.
